

HW1-F25

September 3, 2025

1 ND CBE 60546, Advanced Chemical Reaction Engineering, Fall 2025

1.1 Homework 1

1.2 Due September 5, 2025

Start by sketching out problem and solution approach on paper. If you can solve the problem by hand, do so *neatly*, and either scan your solution and embed the image in your notebook or type the solution into the cell. Otherwise, create python code to solve the problem. Name your variables using meaningful names and liberally comment the solution. Use pyplot or similar package for all plots.

2 All in balance

2.1 One way under consideration for removing harmful “NO_x” (NO + NO₂) from flue gas is the thermal deNO_x process, in which NH₃ is used to reduce the NO to N₂:

2.2 The research lab has several gas tanks available to study this reaction, including one containing 2.0% NO in N₂. You can assume all gases behave ideally.

2.2.1 A number of atoms are changing oxidation state in the thermal deNO_x reaction. Specify the oxidation states of each atom in each molecule.

[]: # Answer here

2.2.2 What type of reaction is this?

[2]: # Answer here

2.2.3 Balance the thermal deNO_x reaction, assuming each NH₃ titrates one NO.

[]: # Answer here

2.2.4 What mass flow rates are necessary to create a stoichiometric mixture at 1 bar total pressure, 400°C, and 10 liter/s total volumetric flow rate?

3 Answer here

3.0.1 Plot the molar flow rates of all five gases as a function of reaction advancement.

[]: # Answer here

3.0.2 Plot the total volumetric flow rate as a function of reaction advancement.

[]: # Answer here

4 NH₃ oxidation is an undesirable side-reaction of thermal de-NO_x:

4.0.1 Balance the NH₃ oxidation reaction.

[]: # Answer here

4.0.2 Under the stoichiometric conditions described above, the reactor generates 0.036 g/s NO and 0.017 g/s N₂. How effectively is the NH₃ being used for thermal deNO_x? (*Hint*: What are the advancements of the two reactions?)

[]: # Answer here
